

Modern logic

Logic was established as a branch of philosophy by Greek philosophers and systematically described by Aristotle (see [Logic and the syllogism](#)). In the form of the syllogism, it survived virtually unaltered until the late 19th century. Change finally came when mathematicians, notably Gottlob Frege, recognized that logic and mathematics are inseparable, and that mathematics consists of arguments and demonstrations based on logic. This inspired a very British school of thought, analytic philosophy, based on the idea that philosophy, too, is derived from logic. Its leading figure, Bertrand Russell, was the first to analyse the language of philosophical statements as logical propositions. The analytical approach influenced philosophers in the

German-speaking world, where it evolved into logical positivism (see [Logical positivism](#)), but Russell's influence was seen most importantly in the linguistic philosophy of Ludwig Wittgenstein. Alongside the philosophical analysis of language, however, there was a growing interest in linguistics as a science, which had its own philosophical implications in turn.
